Mendoza, Gerail C. CFUN

ICT – 101

Journal Module 3: Unit 3

1. In that they diverge from the starting program route in response to a logical condition, loops and branches share this trait. Loops are an effective feature that may be used to streamline programs and make them easier to read. They can be used to carry out repetitive operations, manage a program's flow, and improve program effectiveness. With a loop, on the other hand, you may tell your computer to carry out or repeat an action up until a condition is satisfied.

2. A function returns a value, whereas a procedure does not, and this is the primary distinction between the two.

3. Attributes (fields), properties, and methods

4. Batch files, Windows PowerShell, and Visual Basic Scripting Edition (VBScript).

Batch files - Batch files are a straightforward programming language used to automate processes. They are composed of a string of orders that are carried out one after the other. Frequently, repetitive actions like backing up files or altering system settings are carried out using batch files.

Windows PowerShell - Based on.NET, Windows PowerShell is a more robust scripting language. It offers a large variety of cmdlets (commands) that can be used to manage resources, automate operations, and communicate with Windows. System administrators frequently use Windows PowerShell to carry out difficult administrative tasks.

Visual Basic Scripting Edition (VBScript) - A scripting language based on Visual Basic is called VBScript. Despite having less power than Windows PowerShell, it can still be useful for automating processes. Developers frequently use VBScript to produce scripts that communicate with Windows programs.

5. The information is kept on a server connected to the company's network. As a result of not being accessible via the public internet, the data is more secure and readily available.

Journal Module 3: Unit 4

1. The rows, columns, and data types in the database table are crucial for providing the consistency and accuracy of the data.

2. A query is used to retrieve data from a database, but it can also be used to do computations on the data or to retrieve specific data in order to see information quickly.

3. An RDBMS is a preferable option if you need to store a huge dataset and want great performance and security. Microsoft Excel is a better option if you require flexibility in the data storage and manipulation processes.

4. SQL is a standard language used to access and alter data in relational databases. It is used to manage and query data in the database.

5. A foreign key is a column that points to the primary key of another table in one database. The primary key column's primary key column must match the data type of the foreign key column. The amount of rows in each table that can be linked to one another determines the kind of relationship that exists between them.
