Research Question

What is the relationship between the level of government corruption and the effectiveness of public service delivery in the Philippines?

Justification

Corruption is a persistent and significant issue in the Philippines, affecting governance, economic development, and public trust in institutions. Examining its impact on public service delivery is highly relevant because services such as healthcare, education, and infrastructure directly influence citizens' quality of life. A quantitative analysis can provide empirical evidence on how corruption levels relate to service effectiveness, which can inform policy reforms, anti-corruption strategies, and accountability mechanisms aimed at improving government performance.

Independent and Dependent Variables

The independent variable is the level of government corruption, which can be measured using indicators such as corruption perception scores, reported corruption cases, or audit findings across government agencies or regions. The dependent variable is the effectiveness of public service delivery, which can be measured through quantitative indicators such as service completion rates, budget utilisation efficiency, infrastructure project completion times, or citizen satisfaction survey scores. Analysing these variables allows for measurable comparisons and identification of patterns between corruption levels and service outcomes.
